

Sprint 4 reflection

This sprint, we successfully integrated a whole new UI to improve user experience, created a new home screen, set up filtered outfit planner and screen where users can set filter specifics for top, bottom, shoe, or accessory, and implemented edit feature. As a group, we decided on redesigning our UI to be more efficient for the user by moving the view closet and add item button to the bottom. This way these pages are accessible throughout the whole app. Instead of having to go to the homepage to access different pages, the user will be able to click on icons on a bar on the bottom of the app. Once clicked, they will be redirected to the corresponding page. So far, the buttons lead to the home screen, closet view page, add item screen, and settings. In the future, if we plan on adding any more pages, we will add buttons to access them on the bottom of the page. Moreover, while closet view page, add item screen, and home screen have already been created and designed, we haven't started on the settings page. We plan on adding that in the near future.

After implementing a new UI, we created a new home screen. The previous home screen showed two buttons that would redirect to either closet view or add item screen based on which one was pressed. Since the new UI already implemented those buttons onto the bottom, the user had to be greeted with a new home screen. So, we created a home screen that had top, bottom, and a pair of shoes vertically stacked on each other. On the sides of each piece of clothing, there were arrows that the user can press to change the clothing item. This would give them a little preview of their outfit.

For users wanting to use filters to plan their outfits, we implemented a feature that allows users to click on a category (Top, Bottom, or Shoe) from the default outfit planner, they are redirected to a page displaying all items within that chosen category. This place then serves as the main area where users can apply filters and plan outfits based on their selected preferences.

During this sprint, we worked on implementing the filters feature for the closet and outfit planner. We created the structure where users can click on a filter button and select options like color, brand, and occasion. Once the user selects these options, it filters the clothing items accordingly so they can easily find what they are looking for. We also made sure the filter button fits well with the theme of the app and placed it near the accessory button on the top right corner for easy access. When clicked, it shows categories like Color, Brand, and Occasion, and each category expands to show the available options. We also removed the unnecessary size filters and made the layout simpler and cleaner. Apart from that, we helped connect the navigation flow between the home page, closet, and outfit planner to make the app smoother. We tested the filters several times to make sure they

work properly and look consistent with the overall UI design. Overall, our focus on this sprint was improving the filter functionality and making it user-friendly and visually appealing.

During this sprint, we worked on implementing the edit feature for the closet view and improving the overall functionality and user experience of the app. We created a bottom-sheet interface that allows users to edit, delete, or add new tags to clothing items after they've been uploaded. Each tag is categorized by type such as color, material, or fit; making it easier for users to organize and filter their closet. We also worked on refining the closet page UI so that tag changes update instantly without requiring a page refresh, giving the app a smoother and more dynamic feel. Throughout the sprint, we tested different layouts and adjusted the design to maintain consistency with the rest of the app. Overall, we worked on making the closet experience more interactive, organized, and accessible while improving usability and visual flow across the main sections of the application.

One of the biggest challenges we faced were unclear expectations from the professor. During our third meeting with the professor we felt as though we didn't have much to work with. We kept throwing in ideas and new features we could implement but most of them were shot down. Finally, we suggested a search bar at the top to search through clothing and he seemed to like it. The professor then built on it and suggested we add filters so that the user can filter clothing by for example, color or style. Initially, we didn't like the idea, but when we started working on it, we understood how this could be useful. This still didn't give us enough stuff to work on as a group. So, we decided to focus on the user interface this sprint. The UI was developed around the first sprint. Since we were new to flutter and didn't have much time, we didn't develop it much or put much thought into it. This sprint, we resorted on a whole new design that would make the user experience better and smoother.

Our client told us what he envisioned our app to look like. He thought being able to see the whole closet was too much for the user and that he wanted them filtered. If the user wants only gray tops, they can filter it so that they only see gray tops. He wanted the filters to look like online clothing store and even showed us an example—zappos.com. Our client also suggested a vertical alignment and to present the clothing items in a way that they create an outfit together. He also wanted the user to be able to edit the tags they created when they added a clothing item. The client recommended integrating SQL with firebase and looking into how to build a database. We tried our best to implement as many of these suggestions as we could. This will help with future sprints as we have a better idea of what our client wants and can suggest features that better suit his needs and his understanding.
