

Sprint 5

This sprint, I was responsible for creating a program that suggests clothing items that matches the user's selected piece of clothing. To achieve this, I developed a new class that displays a dialog box where users can click on a suggested item to add to their outfit. I also added a few methods to home_screen class to integrate this functionality and merged the newHome class with the previous home_screen class to create a seamless final homepage. Before merging users could only access the new home screen, but now the navigation bar at the bottom allows them to move between different pages easily.

One challenge I came across was finding a way to suggest clothing items without being intrusive. Initially, the suggestion popup appeared every time the user changed an item, which quickly became frustrating. After exploring alternatives, I decided to trigger suggestions only when the user double clicks on a clothing item, making the experience more user-friendly.

This sprint taught the importance of persistence. When making the new suggestion popup class, my android studio emulator crashed repeatedly. Eventually, I resolved the issue by deleting the Android folder and relaunching the app. This experience reinforced that there is always a solution. This mindset will help me in future sprints when facing similar challenges

Looking back, I could have implemented a more efficient way for users to access suggestions. I considered options like shaking the device or automatically sending a notification, but that felt inconvenient. So, I settled on having the user access the suggestions through double clicking on the clothing item they want a suggestion for. Because this is a hidden feature and users won't know about it right away, I plan to create a demo for new users so they understand how to navigate the app and use the suggestion feature effectively.
