

Sprint 5 review

Accomplishments

New features integrated:

- Suggesting clothing items to the user.
- Outfit history displayed as a list.
- Setup firebase data connect.
- Added button for users to be able to reuse an outfit.
- Create a calendar feature.

Clothing suggestions:

To implement the suggestion feature for each clothing item, we had to create a new class called `suggestion_popup`. The program is designed to suggest clothing items similar in color to the item the user selects. Double clicking on any piece of clothing triggers the suggestion dialog where they can tap on any suggested clothing piece to add it to their outfit.

Clothing history:

Next, we worked on the Clothing history and the Outfit Detail features. We wanted to give the users a better insight into how they actually use their wardrobe over time. When the user clicks on one of the items in their wardrobe, they are redirected to a history screen; there, they are able to see when they wore that item chronologically listed. Moreover, when they click on the chosen date, they can see the outfit they wore on that said date.

Firebase Data Connect:

For Data Connect, we designed our data schema by modeling essential entities and created join tables to support many-to-many relationships, including linking clothing items to various colors or occasions. Then, we implemented the necessary GraphQL mutations and queries to provide full CRUD functionality and support detailed, filtered data retrieval which allowed us to define relationships, configure the schema, and connect our API to a secure and scalable data layer. This groundwork positions us to thoroughly test, validate, and refine Data Connect's behavior in upcoming sprints.

Re-wear Button:

After that, we added a Re-Wear button to the StyleSync app. We worked on this feature so users can quickly log something they wore again without re-uploading it. We added the new

button to the UI and made sure it matches the StyleSync design. We also connected it to Firebase, so it updates the wear history in Firestore with the right timestamp every time it's pressed. We checked that this change didn't break any screens, fixed a few layout issues, and tested everything on the emulator to make sure the app runs smoothly with no crashes.

Calendar:

Finally, we implemented the calendar feature. We first realized that the save button needed for storing planned clothing items had not yet been implemented. Because this was required for this feature, we worked on getting the save functionality working correctly. After that, we added the logic to link saved clothing items to specific calendar dates. This allowed items to be stored and retrieved on each date.

Challenges

A major challenge this sprint was our team's approach of working in separate files to avoid merge conflicts. While it kept version control clean, it made testing and integrating features difficult. I communicated often with teammates and planned integration sessions to solve this. We learned that early branch management prevents integration delays. Overall, I gained technical skills and realized the importance of early planning and communication in collaborative development. We learned that early branch management and scheduled integration sessions are important when working with a team. In the future, we plan on communicating with each other thoroughly to prevent mix ups.

Client Feedback

During our meeting with the client, we proposed adding a suggestion feature, implementing a calendar, and a reuse button.

- The client liked the suggestion feature but worried it would get in the way and disturb the user if it was set up like a notification. So, we opted for a completely different approach where the system wouldn't automatically annoy the user for suggestions, rather the user would tell the system when they wanted it by double clicking on any clothing item in the home screen.
- The client was not as fond of our next idea where the user would be presented with a calendar on a new page. The days on the calendar would be clickable so they can access previously worn outfits on a specific day. Based on this input, we replaced the calendar with an outfit history list and will refine this feature in the next sprint.

- Lastly, we suggested adding a reuse button where the user can click on it to automatically add the whole outfit onto the home screen instead of having to manually remake an outfit from scratch. Although our buyer didn't have much to say on this one, it was clear he was content with it.

Next Steps

- Implement outfit history as a list instead of a calendar.
- Refine the reuse button functionality.
- Continue improving communication and branch management.
