

Sprint 6 review

Accomplishments

New features integrated:

- Tutorial feature for new users
- Finish view history under; a calendar
- Re-Wear feature added to the View History section
- Filtering System w/ Firestore
- Suggestion-limiter

Tutorial:

First, we implemented the tutorial feature to better help new users navigate through the app. By tapping on the help icon on the top right of the home screen, the user is guided through the many features our app provides. Because a lot of our features are hidden, we wanted to make sure users were able to access and learn about them.

Calendar View:

During this sprint, we completed the view calendar feature for our project. We integrated a calendar function in Dart to generate the calendar layout, which eliminated the need to manually create dates and ensured consistency across months as discussed in the customer meeting. Once the saved feature was added, we linked the stored outfit data to the calendar properly. We also broke the calendar view into weekly, bi-weekly, and monthly layouts to give users more flexible ways to navigate their plans. Additionally, we implemented a scrolling arrow for planned outfits on a single day, allowing users to pan through multiple outfits easily.

Re-Wear feature:

We added and integrated the Re-Wear feature into the View History section. This allows users to quickly log outfits they have already worn without needing to upload anything again. When users tap the Re-Wear button, the outfit is saved directly into their wear history with a timestamp, ensuring it appears correctly in both the history and calendar views. This update improves convenience and helps users track repeat outfits more efficiently.

Filtering System w/ Firestore:

We initially explored Firebase Data Connect, but its complexity, setup requirements, and the need to rebuild major parts of our app made it impractical within our time frame. Instead, we optimized our existing Firestore structure by redesigning the clothing item data model to support hierarchical types (itemType -> style -> specificStyles) and using lists for colors and occasions to allow multi-tag filtering. With each attribute stored as a directly querably field, Firestore's where() and arrayContains queries let us efficiently filter items with ease. Cloud Storage handles the images, while Firestore manages all metadata and filtering logic, giving us a flexible, scalable system that fully meets our filtering needs.

Suggestion-Limiter:

We implemented the Suggestion-Limiter to give users more control over the number of clothing recommendations they receive. This feature allows users to turn suggestions on or off entirely and select how frequently they want them delivered. Based on the chosen frequency, a dynamic slider adjusts to let users set the exact number of suggestions they're comfortable receiving within that period.

Challenge:

A major challenge our team came across was that our sprint was due right before thanksgiving break and the artifacts are due the sunday right after. This meant we had to work on the artifacts over the break. Because so many of our teammates were planning on going on vacation, it was challenging to coordinate and get in touch with each other. Everyone was too busy, but after communicating with each other, we prioritized our tasks and successfully finished our assignments.

Feedback

Since we had already so much work on our backlog, we felt meeting with our client was unnecessary. As a group, we decided on working on the tasks that had accumulated in the past sprints. These tasks were those that we hadn't focused on or prioritized because we had enough work to do.

Next Steps

- Use the skills earned throughout the class and apply them in real life.
- With our newly acquired knowledge, we will be successful in coming assignments
- Successfully present our project to the class and satisfy the client.
