

In this sprint, my main contribution was developing the **Suggestion-Limiter** feature. I built the settings interface that allows users to turn suggestions on or off and choose how frequently they want to receive recommendations—per day, per week, or per month. I also implemented the dynamic slider that updates based on the selected frequency, giving users a clear way to set their preferred limit. This work helped move the app toward a more personalized and user-controlled experience.

One of the challenges I encountered was figuring out how to design the feature so it felt simple while still offering multiple modes and options. It took some trial and error to settle on a layout that was clean, intuitive, and expandable for future integration with the suggestion engine. Another challenge was thinking ahead about how these settings will eventually tie into the backend logic. Even though this sprint focused mainly on the UI, I had to ensure the structure was flexible enough to support backend enforcement later. I addressed these difficulties by reviewing similar design patterns and testing a few interface variations before choosing the final approach.

This sprint helped me learn more about building user-centered settings screens and creating UI components that adapt to different modes or states. I also gained a better understanding of how to design features in a way that prepares for future functionality.
